# Direct Alkenylation of Indoles with $\alpha$-Oxo Ketene Dithioacetals: Efficient Synthesis of Indole Alkaloids Meridianin Derivatives** 

Haifeng Yu and Zhengkun Yu*

$\alpha$-Oxo ketene dithioacetals have recently emerged as versatile reagents ${ }^{[1]}$ in the synthesis of heterocycles ${ }^{[2]}$ and aromatic compounds, ${ }^{[3]}$ as well as odorless thiol equivalents. ${ }^{[4]}$ Indole derivatives are potentially bioactive ${ }^{[5]}$ and have been used as synthons of complex molecules. ${ }^{[6]}$ Recently, bisindoles have attracted interest because of their potent antitumor bioactivity. ${ }^{[7,8]}$ Although alkylation and arylation of indoles have been well-documented, ${ }^{[6,9]}$ there are only a few reports on their alkenylation. ${ }^{[10]}$ These alkenylation reactions include palla-dium-catalyzed vinylation using alkenes, ${ }^{[10 a, c]}$ nickel-catalyzed addition of indole to alkynes, ${ }^{[106]}$ acid-promoted reactions, ${ }^{[10 \mathrm{~d}, \mathrm{~g}]}$ or indirect transformations. ${ }^{[10 e, f]}$ Meridianins are marine natural products that represent a new family of protein kinase inhibitors and have been exhibited promising anticancer activity, ${ }^{[11]}$ therefore making their syntheses an attractive challenge. ${ }^{[12]}$ On the basis of the electronic and structural features, we envisioned that $\alpha$-oxo ketene dithioacetals might react with indoles to generate new classes of indole derivatives potentially useful for the synthesis of meridianin derivatives. As a continuation of our interest in the functionalization of indoles, ${ }^{[13]}$ we disclose herein the acid-mediated direct alkenylation of indoles with $2, \alpha$-oxo ketene dithioacetals, providing a new efficient route to derivatives of the meridianin indole alkaloids.

The reaction of $\alpha$-oxo ketene dithioacetal 1a and $N$-methylindole (2a) was initially conducted (Table 1). The first reaction was carried out in trifluoroacetic acid (TFA), which has been reported to be used as the solvent for the electrophilic substitution of arene $\mathrm{C}-\mathrm{H}$ bonds under transi-tion-metal catalysis. ${ }^{[14]}$ The reaction of $\mathbf{1}$ and 2a (1:1 molar ratio) occurred at room temperature, exclusively affording an isomeric mixture of monosubstituted product 3a in $69 \%$ yield within 10 hours (Table 1 , entry 1 ). The reaction proceeded

[a] Reaction conditions: 1a ( 0.5 mmol ), solvent ( 5 mL ). [b] Yield of isolated products. [c] Molar ratio of Z/E-3a isomers determined by ${ }^{1} \mathrm{H}$ NMR analysis. THF = tetrahydrofuran, $\mathrm{Ts}=4$-toluenesulfonyl.
more efficiently to give 3a by using refluxing TFA at $72^{\circ} \mathrm{C}$ (Table 1, entry 2). The reaction run in dichloromethane produced $\mathbf{3 a}$ in a lower yield albeit with a higher stereoselectivity, and unexpectedly, bisindole 4 a was formed in $5 \%$ yield (Table 1, entry 3). A variation of the acidity of the reaction medium, through the reduction of the amount of TFA used, favored the formation of $(Z) \mathbf{- 3 a}$, but the transformation was slower at room temperature (Table 1, entries 3-6). Additional reduction of the amount of TFA in the reaction medium led to $\mathbf{4 a}$ as the major product (Table 1, entries 7 and 8). These results have demonstrated that stronger acidic conditions facilitate the monosubstitution of $\mathbf{1 a}$ by $\mathbf{2 a}$, used in a 1:1 molar ratio, to afford $\mathbf{3 a}$. To obtain 4a in a decent yield, the reaction of $\mathbf{1 a}$ and $\mathbf{2 a}$ in a 1:2 molar ratio was carried out in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ with TFA as the promoter, providing 4a in yields ranging from 86 to $90 \%$ (Table 1, entries 9-13). By using $p$ - TsOH or $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}$ as the acid promoter, the same reaction proceeded but less efficiently (Table 1, entries 14 and 15). The reaction did not occur when THF was used as the solvent (Table 1, entry 16). Accordingly, the reaction conditions were optimized as follows: condi-
tion A: $\mathbf{1} \mathbf{a} / \mathbf{2} \mathbf{a} / \mathrm{TFA}=1: 1: 20$ in refluxing $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ for the synthesis of 3a with a high $Z / E$ ratio; condition $B$ : $\mathbf{1 a} / \mathbf{2 a} /$ TFA $=1: 2: 4$ in refluxing $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ for synthesis of $\mathbf{4 a}$.

Next, the reactions of $2, \alpha$-oxo ketene dithioacetals $\mathbf{1 a - c}$ and indoles 2a-i were carried out under the optimized reaction conditions to define the scope of the reaction (Table 2). The reactions of $\mathbf{1 a}$ and $\mathbf{1 b}$ with $2\left(\mathrm{R}^{3}=H\right)$

Table 2: Alkenylation of indoles with $\alpha$-oxo ketene dithioacetals. ${ }^{[a]}$

steric bulk of the C 2 substituent of $\mathbf{2 h}$ excluded the disubstitution of $\mathbf{1 a}$ to form the expected bisindole $\mathbf{4 n}$. When an electron-withdrawing tosyl group was present (2i) on one nitrogen atom of the indole the reaction of $\mathbf{1 a}$ and $\mathbf{2 i}$ did not occur, suggesting that an electron-withdrawing substituent within 2 decreases its nucleophilicity and thus does not favor its substitution reaction with 1. Product ( $Z$ )-3a was successfully isolated by recrystallization of a ( $Z / E)$-3a mixture, and the molecular structures of $(Z)-\mathbf{3 a}$ and $\mathbf{4 g}$ were confirmed by X-ray crystallographic analysis (Figure 1 and

5a: $\mathrm{R}^{2}=\mathrm{CH}_{3}, 81 \%$
5b: $\mathrm{R}^{2}=\mathrm{H}, 84 \%$
Eq. (1)]. When a bulky group such as phenyl was introduced to the C2-position of the indole (e.g., $\mathbf{2 h}$ ), the reactions of $\mathbf{1 a}$ and $\mathbf{2 h}$ only produced monoindole $\mathbf{3 n}$ (Table 2, entry 14). The

efficiently afforded the mono and bisindole products 3 (64$87 \%$ yield) and 4 ( $61-90 \%$ yield), respectively (Table 2, entries $1-11$ ). The products ( $Z$ )- $\mathbf{3}$ were always obtained as the major products for the reactions run in a $1: 1$ molar ratio, reaching the highest $Z / E$ ratio of $30: 1$ (Table 2 , entry 8 ). Unexpectedly, the 1:1 molar ratio reactions of $\mathbf{1 c}$ with $\mathbf{2 a}$ and $\mathbf{2 d}$ did not give the desired products $\mathbf{3 1}$ and $\mathbf{3 m}$, respectively; instead the hydrolysis products $\mathbf{5 a}$ ( $81 \%$ yield) and $\mathbf{5 b}$ ( $84 \%$ yield), respectively, were formed [Table 2, entries 12 and 13,

(z)-3a
$4 g$

6a
Figure 1. Molecular structures of $(Z)-\mathbf{3 a}, \mathbf{4 g}$, and $\mathbf{6 a}$. The thermal ellipsoids are at $30 \%$ probability.
see the Supporting Information) ${ }^{[19]}$ In $(Z)$-3 a the indolyl and acetyl groups are positioned anti to each other, and in $\mathbf{4 g}$ the two indolyl moieties are arranged in a way so as to reduce the steric interactions by positioning the benzyl groups far away from each other.

The reaction mechanism was explored by studying different substitution reactions of $\mathbf{1 a}$ or $\mathbf{3 a}$ with $\mathbf{2}$. Indoles can be
readily protonated in concentrated acidic solutions, whereas indole dimers are usually formed under dilute acidic conditions. ${ }^{[15,16]}$ Therefore treatment of $\mathbf{2 a}$ in a dilute TFA solution in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature conveniently afforded the dimeric I (see the Supporting Information), which was used to react with $\mathbf{1 a}$ in TFA or under reaction condition B (Scheme 1). Within 30 minutes the reaction of 1a

Scheme 2. Proposed mechanism.
attack at the cationic carbon atom of II by C3 of $\mathbf{2 a}$ forms the $\beta$-indolyl monosubstituted product $\mathbf{3 a}$ via intermediate III by elimination of an EtSH and a proton. In an acidic solution, an equilibrium is present between the indole, its protonated form, and the dimer. ${ }^{[15,16]}$ In concentrated acidic solutions, the protonated indole is predominant and cannot nucleophilically attack carbocation IV to form bisindole 4a, thereby forming 3a when the reactants are used in a 1:1 molar ratio. However, in a dilute acidic solution the readily formed indole dimer easily undergoes thermal conversion into the monomer units, which nucleophilically attack IV to form 4 a as the major product. Notably, 3a may also be protonated by the acid promoter to form III or IV which then reacts with 2 a to generate 4 a.

Meridianins and their derivatives are usually prepared by the condensation of functionalized indoles with guanidines, ${ }^{[12,17 a, b]}$ or by the Suzuki coupling of indolyl boronates with halopyrimidines. ${ }^{[17 \mathrm{cc]}}$ Compounds $\mathbf{3}$ can be considered as ketene monothioacetals or alkenylated indoles which
(2) may be used as versatile synthetic intermedimay be used as versatile synthetic intermedi-
ates. Thus, we carried out the condensation reactions of $\mathbf{3}$ with guanidine, in an attempt to synthesize meridianin derivatives. The reaction synthesize meridianin derivatives. The reaction
of $\mathbf{3 a}$ and guanidine nitrate under basic reaction conditions afforded the meridianin derivative $\mathbf{6 a}$ in $71 \%$ yield upon isolation (Table 3,
entry 1 ), and the $Z / E$ ratio of $\mathbf{3 a}$ did not affect ative $\mathbf{6 a}$ in $71 \%$ yield upon isolation (Table 3,
entry 1 ), and the $Z / E$ ratio of $\mathbf{3}$ a did not affect formation of the desired product. The molecular structure of 6a was confirmed by X-ray crystallographic analysis (Figure 1 and see the Supporting Information). ${ }^{[19]}$ This methodology was also successfully applied to the reactions of $\mathbf{3 b}, \mathbf{3} \mathbf{c}, \mathbf{3 g}-\mathbf{i}$, and $\mathbf{3 k}$, producing the desired products $\mathbf{6 b}-\mathbf{g}$ in yields ranging from 64 to $84 \%$ (Table 3, entries 2-7). Surprisingly, the treatment of $\mathbf{3 d} \mathbf{- f}$, which do not have a protecting group on the nitrogen atom, with guanidine nitrate under the same reaction conditions only gave the deacetylation products $7 \mathbf{a}-\mathbf{c}$
the steric bulk of indole 2 reduces formation of the desired bisindole product. The reactions of $\mathbf{3} \mathbf{a}$ with $\mathbf{2 b}$ or $\mathbf{2 d}$ were also successfully pursued to prepare hetero-bisindoles $\mathbf{4 p}$ and $\mathbf{4 q}$ in approximately a $1: 1 Z / E$ ratio, respectively [Eq. (3)].

A possible mechanism is proposed in Scheme 2. The reaction of $\mathbf{1 a}$ and indole $\mathbf{2 a}$ is presumably initiated by the protonation of the polarized $\mathrm{C}=\mathrm{C}$ bond of $\mathbf{1 a}$ to form carbocation II, which is additionally stabilized by the two adjacent electron-donating ethylthio groups. Nucleophilic

with 0.5 equivalents of $\mathbf{I}$ in refluxing TFA gave 3a in $84 \%$ yield, whereas the treatment of $\mathbf{1 a}$ with 1.0 equivalent of $\mathbf{I}$ in refluxing $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and using TFA as the promoter afforded $4 \mathbf{a}$ in $81 \%$ yield. These results are comparable with those obtained by using 2a as the substrate (Table 2, entry 1 ), presumably because of the facile thermal conversion of the indole dimer into the monomer units. ${ }^{[16]}$ A competition reaction of $\mathbf{1 a}$ with $\mathbf{2 a} / \mathbf{2 b}(\mathbf{2 a} / \mathbf{2 b} 1: 1)$ under intermediate acidic conditions produced homo- and hetero-bisindole products $\mathbf{4 a}, \mathbf{4 b}$, and $\mathbf{4 p}$ [Eq. (2)], revealing that increasing

Table 3: Synthesis of meridianin derivatives from 3. ${ }^{\text {[a] }}$

[a] Reaction conditions for synthesis of 6: $\mathbf{3}$ ( 0.25 mmol ), guanidine nitrate ( 0.5 mmol ), $\mathrm{KOH}(1.5 \mathrm{mmol}), \mathrm{EtOH}(5 \mathrm{~mL})$, reflux, 22 h . Conditions for synthesis of 8: $6(0.25 \mathrm{mmol}) t \mathrm{BuOK}(1.75 \mathrm{mmol})$, DMSO ( 1 mL ), $\mathrm{O}_{2}$ (1 atm), RT, 3-4 h. [b] Yield of isolated product. [Eq. (4)], which suggests that the N -protected ketene monothioacetals of type $\mathbf{3}$ should be used for synthesis of meridianin derivatives. Debenzylation of the $N$-benzyl protected meridianin compounds $\mathbf{6 b}, \mathbf{6 d}, \mathbf{6 f}$, and $\mathbf{6 g}$ with $t \mathrm{BuOK} /$ DMSO under an atmosphere of oxygen ${ }^{[18]}$ afforded N deprotected meridianin derivatives $\mathbf{8 a - d}$ in yields ranging from 76 to $83 \%$ (Table 3, entries 8-11).

In summary, metal-free direct alkenylation of indoles was realized by using acid-mediated substitution reactions of $\alpha$ oxo ketene dithioacetals with indoles, selectively affording $\beta$ indolyl mono- and disubstitituted $\alpha, \beta$-unsaturated carbonyl compounds. Condensation of these indolyl/ketene monothioacetals and guanidine nitrate successfully led to meridianin derivatives.

## Experimental Section

A general procedure for the synthesis of compounds 3. Synthesis of ( $Z / E$ )-4-(ethylthio)-4-(1-methyl-1H-indol-3-yl)but-3-en-2-one ( $Z /$ $E)-\mathbf{3 a})$ : TFA $(0.75 \mathrm{~mL}, 10.0 \mathrm{mmol})$ was added to a stirred solution of $\mathbf{1 a}(95.0 \mathrm{mg}, 0.5 \mathrm{mmol})$ and $\mathbf{2 a}(65.5 \mathrm{mg}, 0.5 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 5 mL ) and then the mixture was refluxed for 30 min until 2 a was completely consumed as determined by TLC methods. Water ( 20 mL ) was then added to the reaction mixture and extracted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(3 \times 15 \mathrm{~mL})$. The combined organic phases were washed with
